No está permitido el empleo de calculadoras programables ni la consulta de libros, apuntes o formularios. Los teléfonos móviles y relojes "smartwatch" deberán permanecer apagados y fuera del alcance del alumno.

La instalación de la figura representa una bomba de calor que toma calor del ambiente (0 $^{\circ}$ C y 95 kPa) en el evaporador y lo cede en el condensador a una corriente de agua para calentar una vivienda. La bomba opera con propano, cuyas tablas se adjuntan. El propano llega al compresor (1) a 3,5 bar como vapor saturado y sale del mismo a 20 bar. El compresor es adiabático y presenta un rendimiento isentrópico del 75%.

A la salida del condensador el propano presenta la misma presión que a la entrada, estando en estado de líquido saturado. El agua (c = 4,18 kJ/kg-K; ρ = 1000 kg/m³) tiene un caudal de 2.150 dm³/h, entrando al condensador a 40 °C y saliendo a 50 °C, sin perder presión.

- a) COP máximo teórico y COP real con el que opera la bomba de calor.
- b) Exergía destruida en el condensador.
- c) Eficiencia exergética de la bomba de calor.
- d) Diagrama T-s del propano, indicando la situación de los puntos 1 a 4 respecto a la campana bifásica.
- e) Diagrama de Sankey (sin valores numéricos) de exergías de la bomba de calor, mostrando todos los elementos (compresor, intercambiadores y válvula).

La instalación de la figura representa un sistema abierto de refrigeración que opera con aire (γ = 1,4; R = 287 J/kg-K) y retira 100 kW de una cámara frigorífica (tomada como un foco a -18 °C). Para ello la turbina aspira aire del ambiente (3) a 35 °C y 95 kPa y lo expande con un rendimiento isentrópico del 80% hasta 12 kPa (4), entrando entonces a un intercambiador de calor que retira el calor de la cámara, saliendo del mismo (1) a – 30 °C sin pérdida de presión. En esas condiciones es aspirado por un compresor adiabático que lo impulsa al ambiente. Al eje que une el compresor con la turbina se acopla también un motor eléctrico (M). La exergía destruída en el compresor es de 95 kW.

La instalación de la figura representa una planta de potencia que opera con aire (γ = 1,4; R = 287 J/kg-K). El aire entra al compresor procedente del ambiente (15 °C y 95 kPa) y sale del mismo a 45 bar, para dirigirse al intercambiador IC donde recibe calor de un foco a 1600 K. Al salir de dicho intercambiador se dirige a una turbina, entrando en la misma a 1200 °C. El aire abandona la turbina y se dirige al ambiente.

El compresor disipa calor al ambiente, operando con una eficiencia exergética del 83%. El proceso en el mismo se puede modelar por una politrópica de n = 1,187. La turbina presenta un rendimiento isentrópico del 92%. El trabajo neto producido por la planta es de 280 MW. Se desprecian las pérdidas de presión en intercambiadores y conductos.

La instalación de la figura representa el ciclo de potencia de una central nuclear de IV generación. El reactor se puede modelar como un foco térmico de 1.100 K que aporta 600 MW al ciclo de potencia mediante el intercambiador IHX.

El ciclo de potencia opera con helio (gas ideal, ver tablas adjuntas; R = 2,08 kJ/kg-K) y presenta unas condiciones de entrada a la turbina (3) de 120 bar y 850 °C. La presión a la salida de la turbina es de 35 bar, operando ésta de forma adiabática y con un rendimiento isentrópcio de 90%. La eficiencia exergética del ciclo es 38,3 %. El ciclo disipa calor al ambiente (15°C y 95 kPa) en el refrigerador, donde el helio circula sin pérdida de presión. El helio entra en el intercambiador IHX (2) a 250 °C, y circula por él sin pérdida de presión.

- a) Rendimiento máximo teórico y rendimiento real del ciclo de potencia.
- b) Exergía destruida en el intercambiador IHX debido al proceso de transferencia de calor.
- c) Potencia consumida por el compresor.
- d) Diagrama T-s del helio, indicando la situación de los puntos 1 a 4.
- e) Diagrama de Sankey (sin valores numéricos) de exergías del ciclo de potencia, mostrando todos los elementos (compresor, intercambiadores y turbina).
